

TOP RANKED BIOMARKER YOU SAY?

Frank Harrell's blog post* on biomarker research illustrates how the common practise of ranking biomarkers by some performance metric can be highly unstable. Inspired by his post, I decided to perform a similar analysis using a subset (60 samples, 200 features) of my own data where we have predictive of a time-to-event. I first calculated apparent ranks using the Cox partial likelihood ratio statistic, and then performed resampling with replacement (200 bootstraps) while re-ranking the analytes within each resample. Take-home message: The data are consistent with the apparent top-ranked analytes taking a wide range of ranks!
